0.5 µm	0.6 µm	shell of porous silica
1.7 µm	3.8 µm	solid core of silicon dioxide
0.5 µm	0.6 µm	shell of porous silica

## Core-shell technology

- Solid core of silicon dioxide, homogeneous shell of porous silica
- Highest efficiency compared to totally porous silica particles
- Particle size 2.7 µm (core 1.7 µm) and 5 µm (core 3.8 µm), pore size 90 Å, specific surface 130 (2.7 µm) and 90 (5 µm) m<sup>2</sup>/g; low back pressure enables use on conventional LC systems
- Pressure stability up to 600 bar

## NUCLEOSHELL® modifications

The program of NUCLEOSHELL® surface modifications now comprises the following phases:

- NUCLEOSHELL® RP 18
- NUCLEOSHELL® RP 18plus NEW!
- NUCLEOSHELL® Phenyl-Hexyl
- NUCLEOSHELL® PFP
- NUCLEOSHELL® HILIC

Several approaches have been made to achieve fast separations without losing chromatographic performance. HPLC columns packed with particles < 2 µm show very high efficiencies (plates/meter) and allow the use of smaller column sizes with the positive side effect of significant solvent saving. However they generate a high back pressure of the mobile phase during column runs which requires specifically designed equipment.

NUCLEOSHELL® core-shell particle technology from MACHEREY-NAGEL is an alternate route to gain highest column efficiency and resolution at almost the same short run time but with much lower back pressure.

NUCLEOSHELL® silica particles consist of a non-porous solid core and a porous outer shell – it is available in two particles sizes, 2.7 and 5 µm, respectively.

With conventional fully porous particles the mass transfer between stationary and mobile phase usually results

in peak broadening at higher flow rates (C-term in van Deemter equation). The short diffusion paths in the core-shell particles reduce the dwell time of the analyte molecules in the stationary phase, so that even at high flow velocities of the mobile phase, optimal separation results can be obtained. The van Deemter plots on page 3 demonstrate how efficiency is affected by flow rate. In comparison with fully porous silicas, core-shell particles from various manufacturers maintain the efficiency optimum (max. plates/m) over a long range of increasing linear mobile phase velocity.

## Theoretical column efficiency (optimal conditions)

Silica phase	d <sub>p</sub> [µm]	L [m]	HETP [µm]	Efficiency [plates/m]	L [mm]	N	R <sub>s</sub>	Analysis time
NUCLEOSHELL®	2.7	1	4	250 000	100	25 000	112 %	40 %
	5	1	6.5	154 000	150	23 000	115 %	60 %
NUCLEODUR®	1.8	1	4.5	222 222	100	22 000	105 %	40 %
	3	1	7.5	133 333	150	20 000	100 %	60 %
	5	1	12.5	80 000	250	20 000	100 %	100 %

## Benefits of core-shell technology

### Short diffusion paths

- Fast mass transfer (term C of Van Deemter equation)
- High flow velocity without peak broadening for fast LC

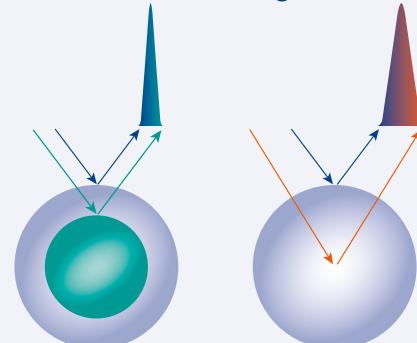

### Narrow particle size distribution ( $d_{90}/d_{10} \sim 1.1$ )

- Stable packing

### High heat transfer

- Minimized influence of frictional heat
- Efficiency of NUCLEOSHELL® ~250 000 m<sup>-1</sup> (HETP ~4 µm)

## Core-shell particles vs. totally porous silica gel

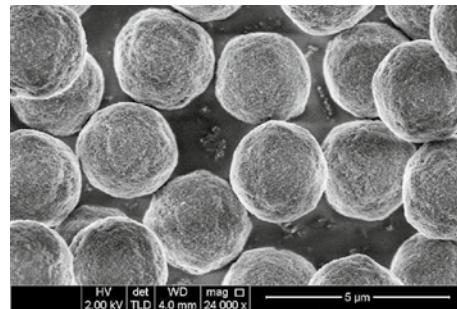

# Core-shell silica

**NUCLEOSHELL®**

Demands on HPLC separations are constantly increasing with respect to separation efficiency, detection limits, and the time requirements for each analysis. Core-shell technology sets new standards for analyses in research and quality control.

$$R_s = \frac{\sqrt{N}}{4} \left( \frac{\alpha - 1}{\alpha} \right) \left( \frac{k_i'}{k_i' + 1} \right)$$

$R_s$  = Resolution  
 $\alpha$  = Selectivity  
 $k_i'$  = Retention  
 $N$  = Theoretical plates  $N \propto 1/d_p$   
 $d_p$  = Particle size

**Electron microscopic image of NUCLEOSHELL® particles**

Utilizing a proprietary process of synthesis, NUCLEOSHELL® particles exhibit a distinct narrow particle size distribution ( $d_{90}/d_{10} \sim 1.1$ ). Columns packed with NUCLEOSHELL® core shell particles feature exceptional separation efficiencies with theoretical plate numbers easily comparable to totally porous sub 2 micron particles.

## Pressure drop

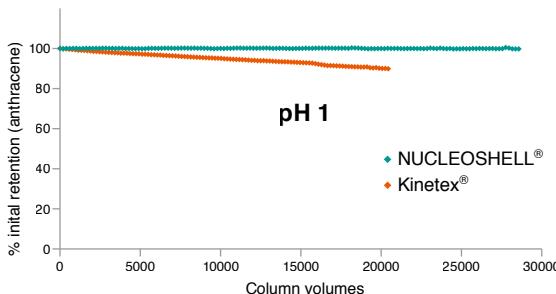

In direct comparison with the “conventional” sub 2 micron phases, NUCLEOSHELL® columns only generate about 60 % of the back pressure and can be operated with the majority of conventional HPLC systems. In order to develop the maximum performance of NUCLEOSHELL® columns, we recommend reducing extra column voids by using suitable capillaries (<0.15 mm inner diameter) and specially adapted detector cells. Moreover detector settings should be optimized by increasing the measuring rate or by decrease of the time constant.

The above figure shows a column stability test of NUCLEOSHELL® RP 18 at mobile phase levels pH 1 and pH 10 compared with three competing phases.

A criterion for the long-term stability of the column at pH extremes is the percentage decrease of initial retention and initial plates, respectively.

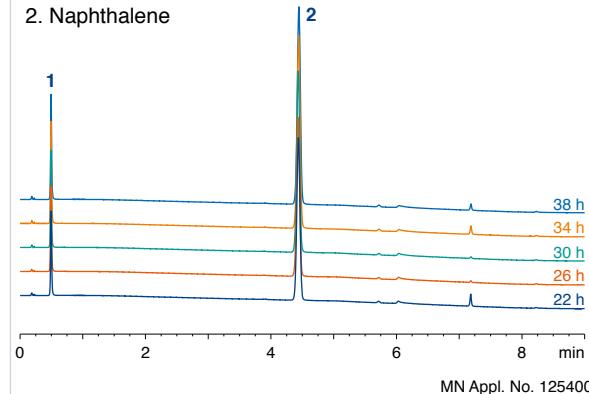

The column can also be operated at elevated temperatures without loss in retention behavior, efficiency or peak symmetry.

## Loading capacity

NUCLEOSHELL® columns allow **reliable quantification** in a wide analytical detection range. Retention time and peak width at 50 % height remain constant with increasing column load although core-shell particles are suspected of showing a slightly lower loading capacity compared to fully porous silica materials.

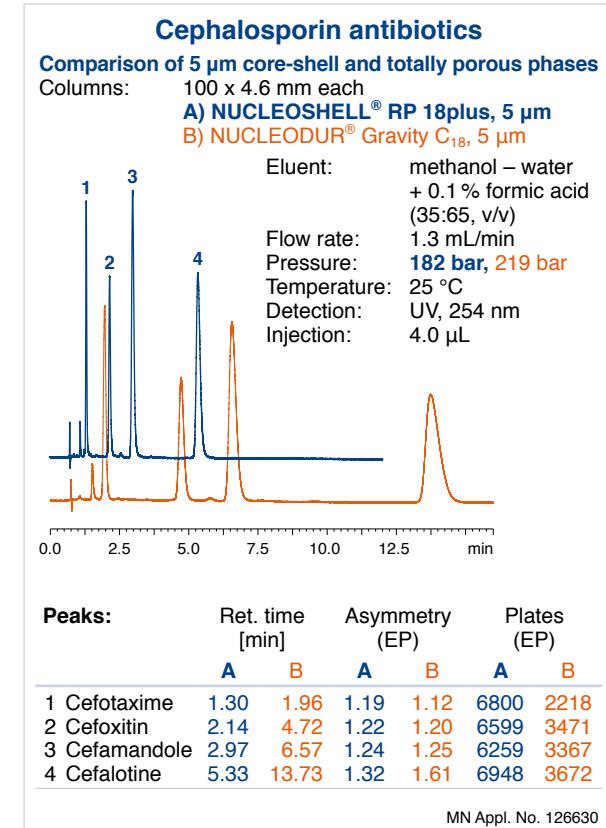

## Peak capacity

The peak capacity is a measure of the number of sample analytes that can be separated on HPLC columns per time unit. Narrow peaks increase the peak capacity and efficiency of analytical columns. The example shows, that in comparison with totally porous NUCLEODUR® silica (1.8 µm) NUCLEOSHELL® provides 33 % higher peak capacity.

## Method transfer of 5 µm particle columns

NUCLEOSHELL® is also available in 5 µm particle size to offer all benefits of core-shell technology to all applications which are bound to particle size.

# NUCLEOSHELL® RP 18

## Key features:

- Based on core-shell particle technology for fast and efficient HPLC
- Suitable for LC/MS and HPLC at pH extremes (pH 1–11)
- Superior base deactivation, ideal for method development

## Technical characteristics:

Octadecyl modification, multi-endcapped; pore size 90 Å, available particle sizes 2.7 µm and 5 µm, carbon content 7.8 % for 2.7 µm, 6.1 % for 5 µm

## Recommended application:

Overall sophisticated analytical separations, e.g., analgesics, anti-inflammatory drugs, antidepressants; herbicides; phytopharmaceuticals; immunosuppressants

USP L1

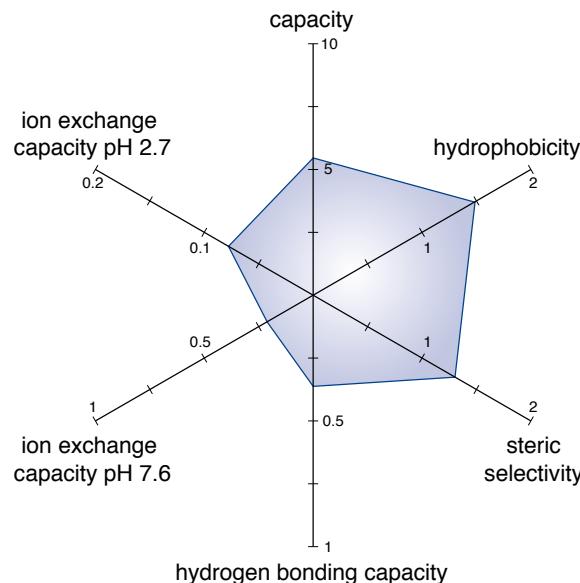

## NUCLEOSHELL® RP 18

NUCLEOSHELL® RP 18 is based on core-shell particle technology silica. A unique derivatization process generates a homogeneous surface with a high density of bonded silanes (carbon content 7.8 % for 2.7 µm, 6.1 % for 5 µm). The following thorough endcapping suppresses any unwanted polar interactions between the silica surface and the sample, which makes NUCLEOSHELL® RP 18 particularly suitable for the separation of basic and other ionizable analytes.

The extremely reduced silanol activity of the phase can be demonstrated by applying basic analytes, such as tricyclic antidepressants. The chromatogram on page 7 shows a sharp elution profile (superior resolution!) of these highly polar compounds with an excellent asymmetry value for amitriptyline of 1.12.

NUCLEOSHELL® RP 18 combines innovative silica technology and excellent surface deactivation, that outperforms conventional C<sub>18</sub> silicas in terms of efficiency, resolution and speed. Due to the applied core-shell particle design the back pressure at elevated flow rates remains at a moderate level and permits the use of existing HPLC equipment in many cases.

**NUCLEOSHELL® RP 18 with extended pH stability, low bleed characteristics in LC/MS applications and overall robustness is an ideal tool for method development and routine analysis in modern HPLC.**

# NUCLEOSHELL® RP 18plus

## Key features:

- Based on core-shell particle technology for fast and efficient HPLC
- Hydrophobic C<sub>18</sub> phase with distinct polar selectivity, ideal for method development
- Excellent performance under highly aqueous conditions

## Technical characteristics:

USP L1

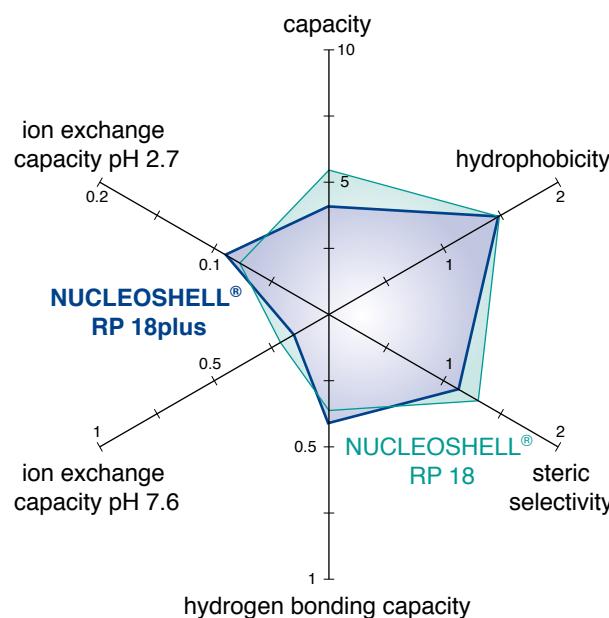

## NUCLEOSHELL® RP 18plus

NUCLEOSHELL® PR 18plus is a C<sub>18</sub> modified core-shell silica. Due to a monomeric bonding chemistry this HPLC phase offers hydrophobic characteristics with distinct polar selectivity. A special derivatization process generates a medium density of bonded silanes (carbon content 5.7 % for 2.7 µm, 4.4 % for 5 µm) with reduced steric selectivity compared to NUCLEOSHELL® RP 18. Due to its low bleeding characteristics NUCLEOSHELL® RP 18plus is suitable for LC/MS applications.

## Tanaka plot of NUCLEOSHELL® RP 18plus

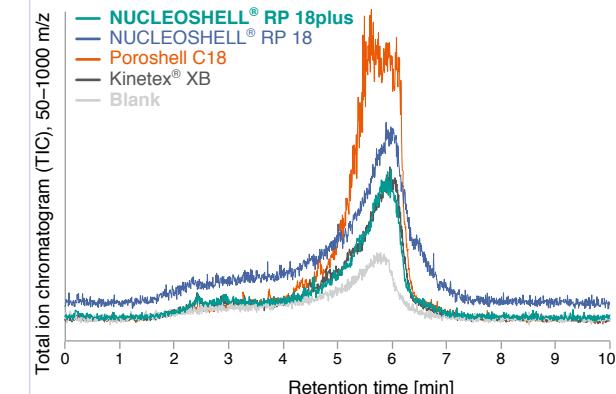

The more polar characteristics of NUCLEOSHELL® RP 18plus compared to NUCLEOSHELL RP 18 are demonstrated by the lower capacity (retention of pentylbenzene). Also a comparison of retention of the glycopeptide antibiotic vancomycin on several octadecyl modified core-shell phases (page 9) underlines the polar selectivity of NUCLEOSHELL® RP 18plus.

The extremely reduced silanol activity of the phase can be demonstrated by the low ion exchange capacity at pH 7.6 which indicates excellent endcapping (for parameters of the Tanaka plot see page 6). The radar diagram also shows that the monomeric bonding chemistry results in a thinner carbon coating and less steric selectivity.

On NUCLEOSHELL® Phenyl-Hexyl the resolution of the last two peaks is higher than on the fully porous 1.8 µm NUCLEODUR® Phenyl-Hexyl.

The separation of sulfonamides proves the scalability from fully porous NUCLEODUR® to NUCLEOSHELL® Phenyl-Hexyl. Hereby the core-shell silica exhibits under same conditions identical selectivity, narrower peaks and slightly shorter retention. Thus, method transferability between NUCLEODUR® and NUCLEOSHELL® is guaranteed, either for speeding up your methods or

scaling up for preparative requirements. The pyridine-phenol test shows that NUCLEOSHELL® Phenyl-Hexyl provides a symmetrical peak for pyridine and higher resolution in comparison to other core-shell based Phenyl-Hexyl phases, which underlines the excellent base deactivation.

## Recommended application:

Aromatic and unsaturated compounds, phenols, halogenated compounds, isomers, polar compounds like pharmaceuticals, antibiotics; high retention of basic compounds

**USP L43**

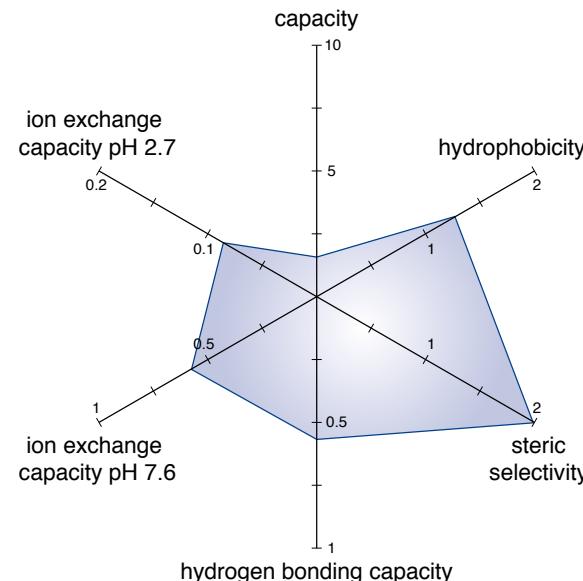

## Orthogonality in selectivity

Fluorinated stationary phases in HPLC have gained increasing interest over the last years. Most common representative of fluorinated silica phases is the pentafluorophenyl modification (PFP or F<sub>5</sub>). Especially the orthogonal selectivity compared to traditional alkyl phases widens the scope in analytical HPLC. Thus NUCLEOSHELL® PFP offers an excellent selectivity especially for highly polar analytes, aromatic and unsaturated compounds, phenols or halogenated hydrocarbons.

Halogen substitutes in molecules result often in an increase of their polarity accompanied by a decrease of typical retention characteristics in RP-HPLC.

While a typical C<sub>18</sub> phase just provides hydrophobic interactions between stationary phase and analyte NUCLEOSHELL® PFP offers four different retention mechanisms: polar interactions (H bonds), dipole-dipole interactions, π-π interactions and hydrophobic interactions. Especially the pronounced ion exchange capacity and distinct steric selectivity are typical for the character of fluorinated phases.

# NUCLEOSHELL® HILIC

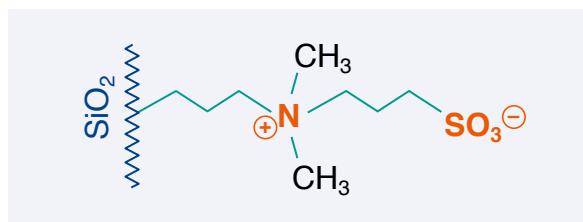

## NUCLEOSHELL® HILIC

Hydrophilic interaction chromatography (HILIC) is a separation technique using polar stationary phases and organic-aqueous mobile phases. A minimum water content of at least 2 % is indispensable to provide a permanent water layer between the adsorbent surface and the organic fraction of the mobile phase. The sample molecules become separated in a partition chromatography, in which polar analytes are more strongly retained than neutral, less hydrophilic compounds. Consequently, increasing the aqueous part in the mobile phase will diminish retention of the polar sample constituents. In this way HILIC behaves inverse to classical RP chromatography. The particular retention profile of HILIC enables the chromatography of very polar and often small molecules, which won't show any retention on C<sub>8</sub> or C<sub>18</sub> reversed phases.

### Ultra-fast separations at moderate back pressure

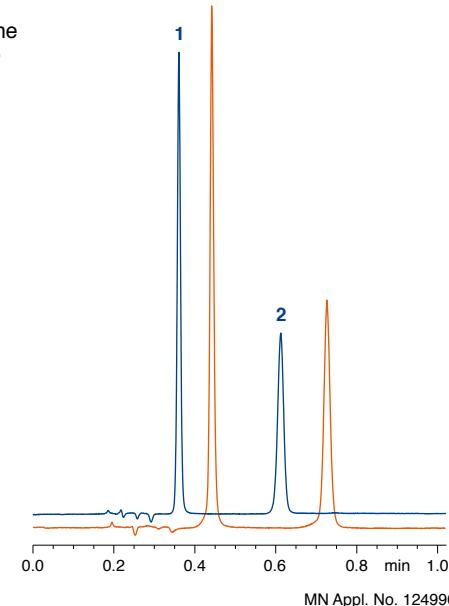

NUCLEOSHELL® HILIC is a core-shell technology based stationary phase with a covalently bonded 3-N,N-dimethylaminopropane sulfonic acid ligand (pat. pend.). The betaine character of the strong ion-exchanger results in full charge balancing and facilitates fast equilibration times.

Good separation of polar compounds like the physiologically important substances creatine and creatinine can be achieved on NUCLEOSHELL® HILIC as well as on NUCLEODUR® HILIC, 1.8 µm at similar retention, but much lower back pressure.

The chromatograms show the method transfer from a fully porous 3 µm HILIC phase to 2.7 µm core-shell silica with equal selectivity features. Run time has been cut

down to 1 min. Column back pressure remains modest < 400 bar, while solvent demand is reduced to less than 35 %.

**NUCLEOSHELL® HILIC provides stable and reproducible chromatography, comprising all the benefits of a state-of-the-art core-shell silica.**

## Column Protection System

Innovative and universal screw-on guard column holder system

Suitable for all analytical HPLC columns with 1/16" fittings

- Cartridges filled with specified NUCLEOSHELL®, NUCLEODUR®, and NUCLEOSIL® HPLC adsorbents
- Ideal protection for your analytical main column → significant increase in column lifetime
- Minimized void volume → suitable also for ultra fast HPLC
- Special ferrules → pressure stability up to 1034 bar (15 000 psi)
- Visual contamination check → in-time changing of the guard column
- Guard column length 4 mm, ID 2 mm (for main columns with 2 mm ID) or ID 3 mm (for main columns with 3, 4 and 4.6 mm ID)
- UNIVERSAL RP guard columns available for all HPLC columns under RP conditions

### Contamination check

The cartridge is fitted with a special filter membrane.

If the silver membrane is contaminated (bright or dark discolouration), it is advisable to replace the cartridge.

If the contaminants are colorless, replace the cartridge as soon as the pressure rises or the chromatographic performance decreases.

## EC standard columns for analytical HPLC

- Analytical column system made of stainless steel M 8 outer threads on both ends Combination of sealing element and very fine-meshed stainless steel screen, PTFE ring and fitting adapter Column heads SW 12, with inner threads M8 x 0.75 and UNF 10-32 (= 1/16" fitting)
- EC column hardware guarantees pressure stability of 1200 bar - hence EC columns are suitable for U-HPLC applications (ultra fast HPLC) and all modern HPLC systems.
- As screw-on guard column system we recommend the **Column Protection System** used with EC guard column cartridges with 4 mm length (see page 25).
